2nd highest — automate more

# Average Task Duration by Phase

Hours spent per task, averaged across all sprints

# Analysis

## Development — Primary Bottleneck

At 6.8 hrs, development consumes the most time. Modular planning and targeted code reviews can reduce cycle time significantly.

## Design — Moderate Risk

3.9 hrs is manageable but improving requirement clarity upfront will reduce rework and speed up the design phase.

## Testing — Automation Opportunity

4.8 hrs average signals heavy manual testing. CI/CD pipelines and automated test suites can cut this nearly in half.

## Deployment — Efficient

2.9 hrs is the fastest stage. Current DevOps practices are working well — maintain with monitoring and dashboards.

# Recommendations

*Priority actions to reduce task duration and improve throughput*

## 01 Modular Development Planning

Break large tasks into smaller, well-defined units. Conduct structured code reviews to catch issues early and reduce rework.

## 03 Sharpen Design Requirements

Invest in clearer briefs and design specs before work begins. Reduce design iterations caused by ambiguous scope.

## 02 Implement CI/CD Pipelines

Automate test pipelines and deployments. Target 50%+ reduction in manual testing effort using automated regression suites.

## 04 Sustain Deployment Efficiency

Keep monitoring in place. Document current deployment practices as a playbook to maintain speed as the team scales.
